Selection sort

CodEx — Exercices de programmation

Write a function `tri_selection(tableau)` that sorts a list of integers `tableau` *in place* (the list is modified), in increasing order.

Use the following algorithm : go through the list from left to right ; at each position, find the minimum of the list between this position and the end, then swap these two values.

Examples : after `tri_selection(tab)` with `tab = [1, 52, 6, -9, 12]`, `tab` is `[-9, 1, 6, 12, 52]` ; an empty list stays empty ; `[9]` stays `[9]`.
