Bubble sort

CodEx — Exercices de programmation

Principle of bubble sort : go through the list and swap two consecutive elements if they are not in the right order. After $n-1$ such passes (n is the length), the list is sorted.

Simplification : after the first pass, the largest value is in the last position, which is its final place ; on the next pass one therefore stops at the second-to-last element, and so on.

Write a function `tri_bulles(nombres)` that sorts the list of integers `nombres` in place with this algorithm. It returns nothing and uses no other list.

Examples : `[2, 11, 3, 7, 5]` becomes `[2, 3, 5, 7, 11]` ; `[42]` and `[]` do not change.
