GCD by Euclid's algorithm

CodEx — Exercices de programmation

The GCD of two positive integers a and b is the largest positive integer dividing both a and b. For example, the GCD of 18 and 24 is 6, that of 20 and 10 is 10, that of 28 and 15 is 1.

Performing the Euclidean division of a by b means finding non-negative integers q and r such that $a = bq + r$ and $0 \leq r < b$; in Python, the remainder r is the value of `a % b`.

Write a function `pgcd(a, b)` that returns the GCD of two positive integers, without using the function `gcd` of the `math` module. Euclid's algorithm : compute the remainder r of the division of a by b ; while r is not zero, a takes the value of b, b that of r, and the remainder is computed again. When r is zero, the GCD is b.
