Binary search

CodEx — Exercices de programmation

Write a function `est_present(nombres, cible)` that takes a list of integers `nombres` sorted in increasing order and a value `cible`, and returns `True` if `cible` is a value of `nombres`, `False` otherwise.

The binary search algorithm is compulsory : you must not read more than half of the values of `nombres`, nor use the test `cible in nombres`.

Examples : `est_present([1, 2, 3, 4], 2)`, `est_present([1, 2, 3, 4], 1)`, `est_present([1, 2, 3, 4], 4)` and `est_present([1], 1)` are `True` ; `est_present([1, 2, 3, 4], 5)`, `est_present([1, 2, 3, 4], 0)`, `est_present([1], 0)` and `est_present([], 1)` are `False`.
