Transformation Geometry — problem 12.2.9

A. Engel — Problem-Solving Strategies · 1998

Assume a line a and a point P. Using as few lines as possible (circles or segments), construct the line perpendicular to a which passes through P. If $P \notin a$ the problem is well known to every high school student of geometry. But suppose $P \in a$. The minimal construction is hardly known. See the solution for a proof of our contention.
